

## ENTERPRISE CYBER AUTOMATION CASE STUDY

# From Raw Cyber Data to Structured Analysis

A large organization needed a faster and more consistent way to analyze host and operational data without sending sensitive information to a public AI service. GS Consulting designed and implemented the complete private AI automation pipeline.

### Private deployment

A locally hosted model kept processing inside the approved environment.

### Structured integration

Defined JSON moved analysis into an approved SIEM or database.

### Operational control

Orchestration, validation, logging, and human review surrounded the model.

Public case study: <https://gsconsultingllc.com/case-studies/private-ai-cyber-analysis-automation>

EXECUTIVE SNAPSHOT

# The System at a Glance

The model mattered. The operating system around it made the analysis usable.

|                                                                                                                                                         |                                                                                                                                               |
|---------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA SOURCES</b><br><b>Host and operational data</b><br>One automated processing model for multiple collection categories.                           | <b>AI DEPLOYMENT</b><br><b>Locally hosted and controlled</b><br>Sensitive operational data remained within the approved environment.          |
| <b>DOMAIN INTELLIGENCE</b><br><b>Codified cyber analysis knowledge</b><br>Organizational methods became repeatable analysis instructions.               | <b>AUTOMATION</b><br><b>Custom Python pipeline</b><br>Discovery, preparation, model interaction, output handling, and routing were automated. |
| <b>OPERATIONAL INTEGRATION</b><br><b>Structured JSON in a SIEM or database</b><br>AI analysis became searchable inside an existing enterprise platform. | <b>ORCHESTRATION</b><br><b>Workflow control plane</b><br>The organization gained visibility into processing state and failures.               |

*The implementation crossed cyber analysis, Python automation, local model deployment, knowledge design, structured data generation, enterprise integration, workflow orchestration, and operational controls.*

Customer identity, sensitive prompts, exact configurations, model details, and quantitative performance results are intentionally omitted from the public case study.

THE CHALLENGE

# The Problem Was Bigger Than Running Data Through a Model

The organization had multiple collection categories, many artifacts, sensitive information, specialized methods, and an operational platform that expected structured data.

The existing process required people to locate files, identify collection type, prepare material, apply domain knowledge, write analysis, reshape the result, move it into another system, and verify completion. Each step served a purpose, but repeated handling limited scale and visibility.

***A model response is not an operational capability. The capability comes from everything surrounding the model.***

BEYOND THE PROOF OF CONCEPT

# This Could Not Be Solved With a Chat Window

The difficult work was not getting the model to produce text. It was turning model output into a controlled enterprise process.

| NOT ENOUGH                                                                                                                       | OPERATIONAL REQUIREMENT                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Install a model</b><br>A model by itself does not account for environment, task, hardware, context, or operating constraints. | <b>Configure for the environment</b><br>Align the model and settings to the approved boundary, task, hardware, context, and operating constraints. |
| <b>Write a prompt</b><br>A single prompt does not preserve specialized methods across diverse collection categories.             | <b>Codify repeatable methods</b><br>Translate approved cyber analysis knowledge into reusable, category-specific instructions.                     |
| <b>Produce an answer</b><br>Free-form prose cannot reliably support downstream automation.                                       | <b>Return validated structured data</b><br>Require defined JSON, check the schema, and route exceptions for review.                                |
| <b>Run a script</b><br>One script does not provide shared execution state, recovery, or operational visibility.                  | <b>Operate an orchestrated workflow</b><br>Manage execution, failures, logging, workload state, integrations, and human control.                   |

## A Model Response Is Not an Operational Capability

The difference is the controlled system around the model: data, software, schema, orchestration, integration, and review.

SOLUTION ARCHITECTURE

# GS Consulting Built the Complete Pipeline

One GS Consulting technical principal owned the architecture from raw collection through indexed analysis.

|    |                                                                                                                       |
|----|-----------------------------------------------------------------------------------------------------------------------|
| 01 | <b>Data source identification</b><br>Discover eligible artifacts and route each collection category correctly.        |
| 02 | <b>Python automation</b><br>Prepare inputs, control model calls, capture responses, and handle errors.                |
| 03 | <b>Private model deployment</b><br>Execute locally with task-aligned configuration inside the controlled environment. |
| 04 | <b>Codified cyber expertise</b><br>Apply repeatable, collection-specific organizational methods.                      |
| 05 | <b>Structured JSON output</b><br>Return required fields that can be validated and ingested.                           |
| 06 | <b>SIEM or database integration</b><br>Index analysis inside an approved platform already used by analysts.           |
| 07 | <b>Workflow orchestration</b><br>Expose execution state, failures, and work requiring attention.                      |

*Orchestration and human oversight span the complete pipeline; they are not final boxes added after the model.*

EXECUTION AND CONTROL

# How the Automated Workflow Runs

Each stage has a defined job. No single stage carries the complete capability.

|                                                                |                                                                            |
|----------------------------------------------------------------|----------------------------------------------------------------------------|
| <b>01 Detect</b><br>Identify relevant collection artifacts.    | <b>02 Classify</b><br>Select the correct collection path.                  |
| <b>03 Prepare</b><br>Read and prepare approved content.        | <b>04 Analyze</b><br>Apply private model execution and cyber instructions. |
| <b>05 Structure</b><br>Return analysis in defined JSON.        | <b>06 Validate</b><br>Check structure and capture exceptions.              |
| <b>07 Orchestrate</b><br>Track workflows, state, and failures. | <b>08 Operationalize</b><br>Ingest and index the result.                   |

## Automation Without Control Is Not an Enterprise Solution

|                                                    |                                                               |
|----------------------------------------------------|---------------------------------------------------------------|
| - Data routing and approved processing eligibility | - Task-aligned model settings and context management          |
| - Structured output and schema validation          | - Error capture, workflow state, and operational logging      |
| - Workload execution and failure visibility        | - Human review for interpretation and consequential decisions |

OPERATING MODEL AND OUTCOMES

# From a Fragmented Process to an Operational System

The improvement came from connecting the process, not from treating the model as the product.

## From Fragmented Processing to an Operational System

Automation reduced repetitive handling while improving consistency, integration, and process visibility.

BEFORE

### Fragmented processing

- Manual artifact discovery
- Separate handling by data type
- Knowledge held in individual memory
- Unstructured analysis output
- Manual transfer into operations
- Status checked across disconnected steps

AFTER

### An observable operational system

- ✔ Automated discovery and routing
- ✔ Collection specific processing paths
- ✔ Codified cyber analysis methods
- ✔ Defined JSON ready for validation
- ✔ Direct SIEM or database indexing
- ✔ Workflow orchestrator visibility

Capacity can grow without manual handling growing at the same rate

Source: GS Consulting implementation summary. Client and operational details are anonymized.

GS Consulting Case Study

|                                                                                                                                                   |                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Greater analysis capacity</b><br>More collection material can move through the system without repetitive handling increasing at the same rate. | <b>More consistent analysis</b><br>Collection-specific instructions help apply approved methods consistently across repeated tasks.               |
| <b>Preserved institutional knowledge</b><br>Analysis methods became a reusable system asset rather than remaining only in individual experience.  | <b>Faster operational availability</b><br>Structured results can move into a SIEM or database without extensive reformatting and manual transfer. |
| <b>Better visibility</b><br>Workflows, execution state, and failures can be observed from a shared control plane.                                 | <b>Greater data control</b><br>Model processing remained inside the approved local environment.                                                   |

*The system increased analyst capacity. It did not remove human responsibility for review, investigation, exceptions, or consequential decisions.*

IMPLEMENTATION DEPTH

# One Architect Across the Complete System

Most organizations can find specialists in one or two areas. This implementation required one coherent architecture across all five.

|                                                                                                       |                                                                                                                 |
|-------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Cyber expertise</b><br>Useful logic for different host and operational data categories.            | <b>AI engineering</b><br>Model selection, deployment, configuration, and control.                               |
| <b>Software engineering</b><br>Custom Python, data handling, structured output, and error management. | <b>Enterprise integration</b><br>Operationally useful analysis inside a SIEM or database.                       |
| <b>Orchestration</b><br>Workflow definitions, execution state, and shared visibility.                 | <b>Human oversight</b><br>People retain authority over interpretation, exceptions, and consequential decisions. |

DESIGNED AND IMPLEMENTED BY GS CONSULTING

## Chris Seymour, Co-Founder and Principal

Chris works across secure AI, cybersecurity software, automation, infrastructure, testing, deployment, and enterprise integration. He independently designed and implemented the system described in this case study.

*The most useful AI engineering work crosses application code, infrastructure, testing, security controls, deployment, and operations.*
